Reinforcement learning (RL)

In RL, an agent learns by interacting with an *unknown* environment through trial-and-error to maximize long-term total reward.

What is RLHF?

ChatGPT
RLHF stands for Reinforcement Learning from Human Feedback. It's a technique used in machine learning and artificial intelligence where a model learns to perform tasks or make decisions based on feedback from human trainers, rather than solely relying on pre-existing data sets or explicit programming. This approach allows the

Single-agent Q-learning

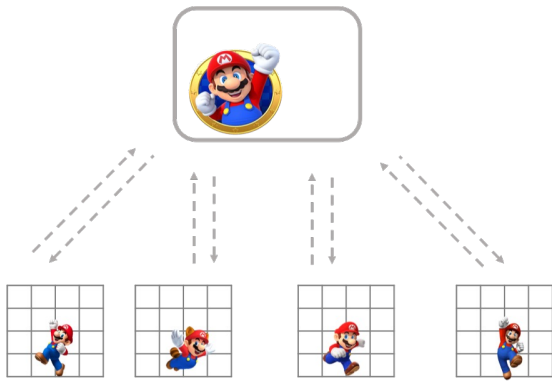
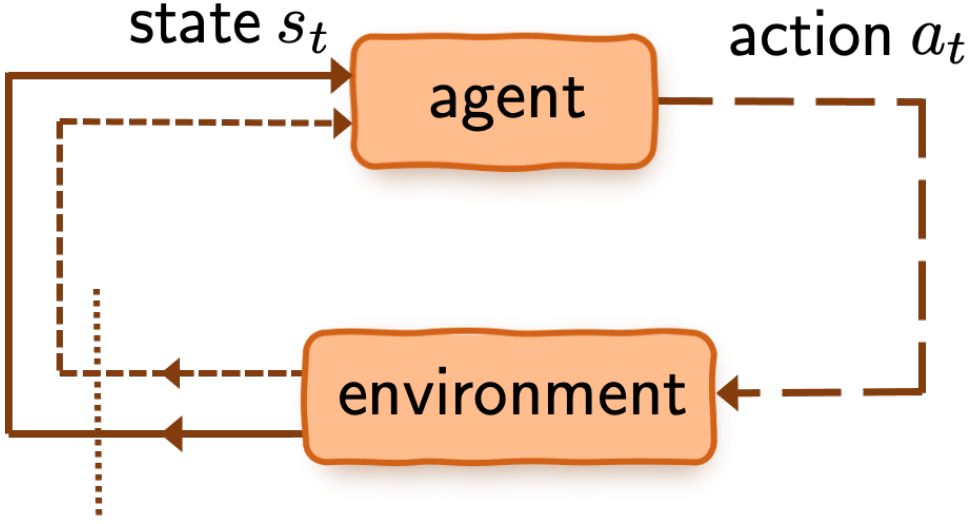
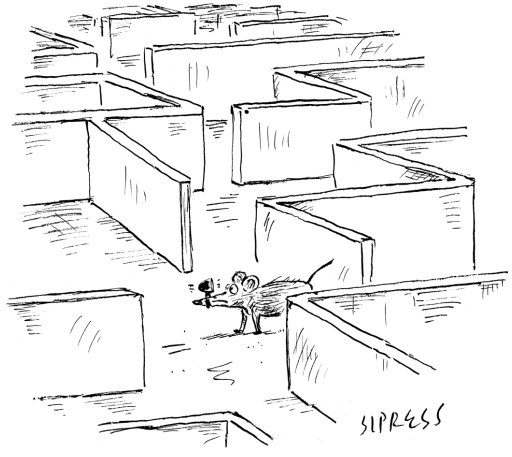
Federated Q-learning



Backgrounds:
Markov decision processes

Markov decision process (MDP)

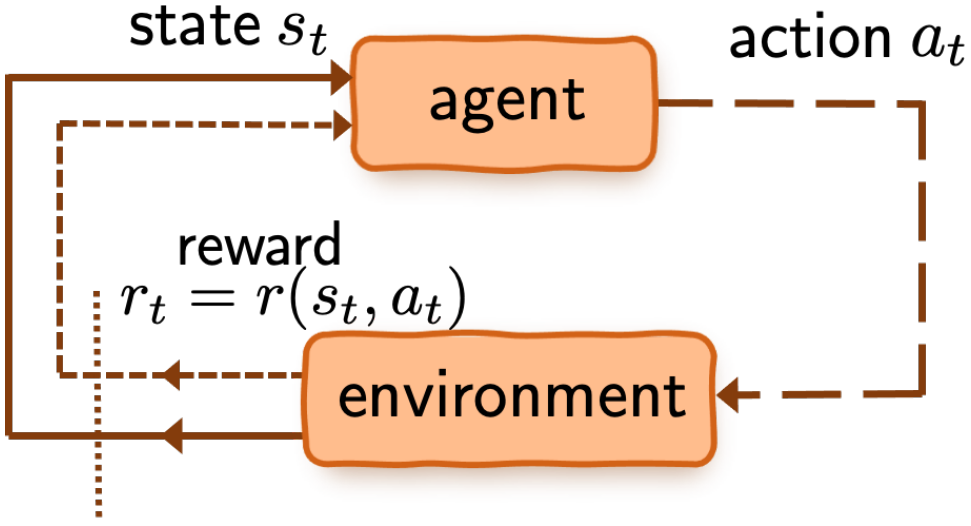


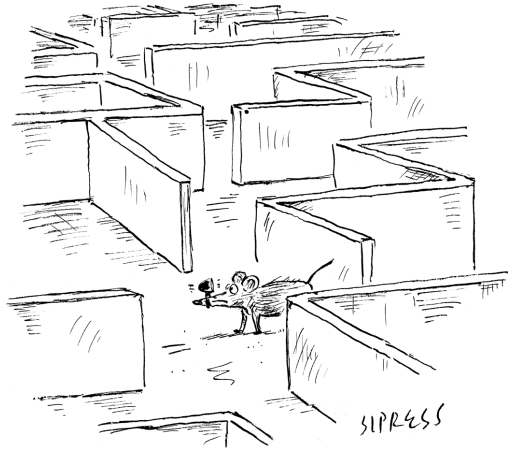


"Recalculating ... recalculating ..."

- $\mathcal{S}$: state space
- $\mathcal{A}$: action space

Markov decision process (MDP)

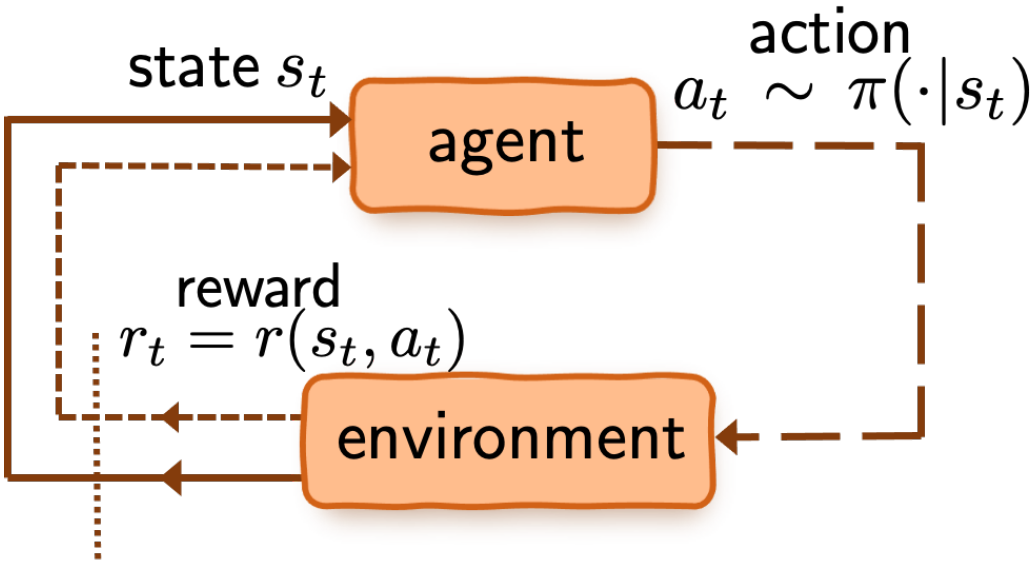




"Recalculating ... recalculating ..."

- $\mathcal{S}$: state space
- $\mathcal{A}$: action space
- $r(s, a) \in [0, 1]$: immediate reward

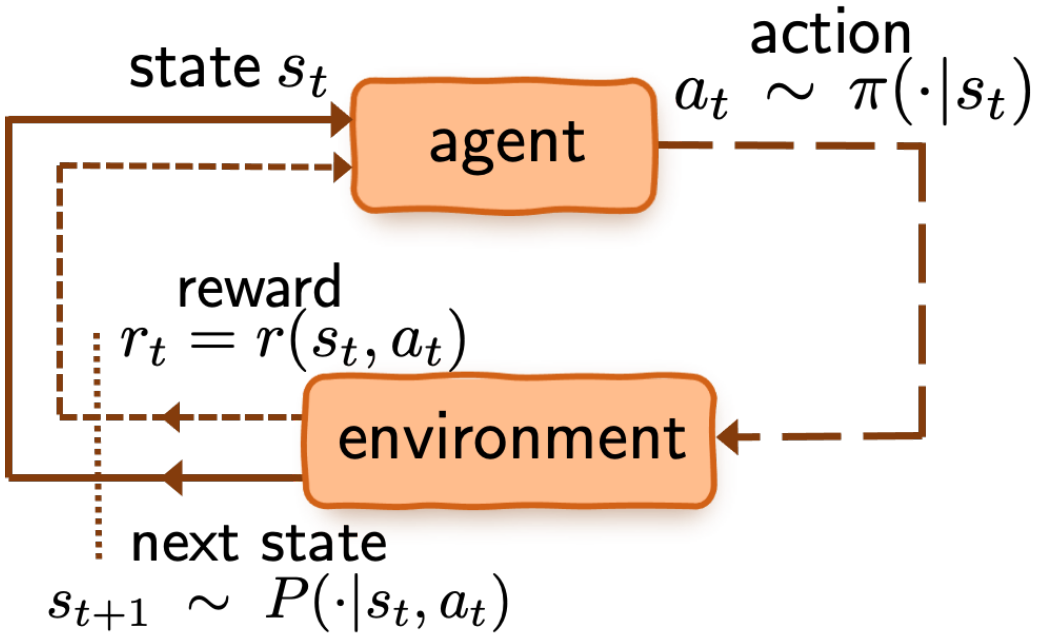
Markov decision process (MDP)



"Recalculating ... recalculating ..."

- $\mathcal{S}$: state space
- $\mathcal{A}$: action space
- $r(s, a) \in [0, 1]$: immediate reward
- $\pi(\cdot|s)$: policy (or action selection rule)

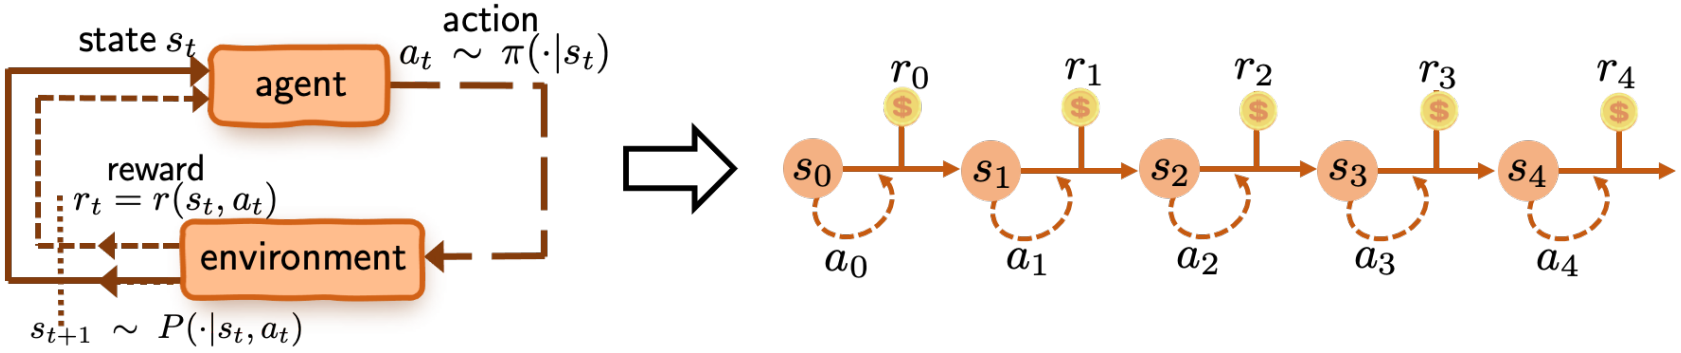
Markov decision process (MDP)



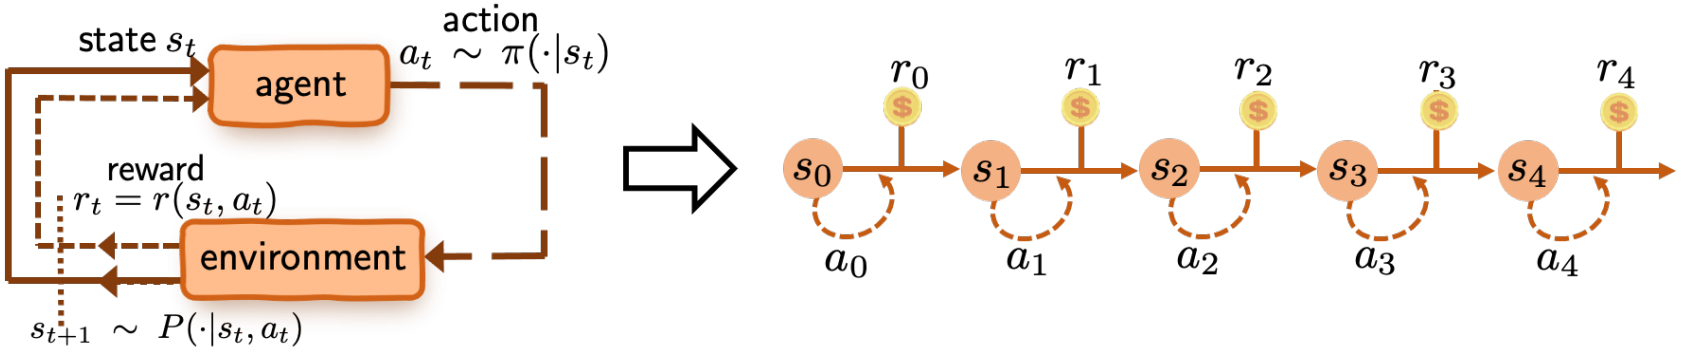
"Recalculating ... recalculating ..."

- $\mathcal{S}$: state space
- $\mathcal{A}$: action space
- $r(s, a) \in [0, 1]$: immediate reward
- $\pi(\cdot|s)$: policy (or action selection rule)
- $P(\cdot|s, a)$: transition probabilities

Value function



Value function



Value function of policy π:

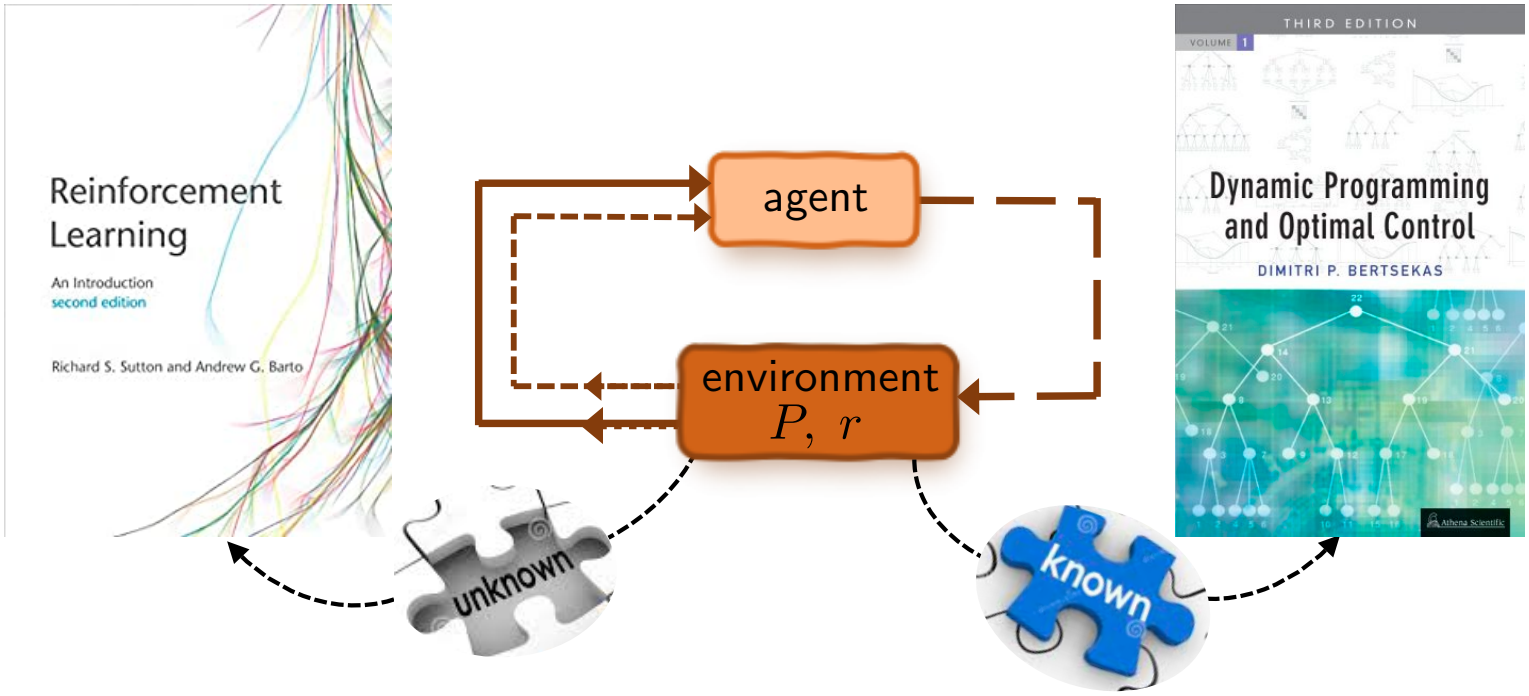
$$\forall s \in \mathcal{S}: \qquad V^\pi(s) := \mathbb{E}\left[\sum_{t=0}^{\infty} \gamma^t r_t \,\middle|\, s_0 = s\right]$$

Q-function of policy π:

$$\forall (s,a) \in \mathcal{S} \times \mathcal{A}: \quad Q^\pi(s,a) := \mathbb{E}\left[\sum_{t=0}^{\infty} \gamma^t r(s_t, a_t) \,\middle|\, s_0 = s, a_0 = a\right]$$

- $\gamma \in [0,1)$ is the discount factor; $\frac{1}{1-\gamma}$ is effective horizon
- Expectation is w.r.t. the sampled trajectory under π

Searching for the optimal policy



Goal: find the optimal policy $\pi^\star$ that maximize $V^\pi(s)$

- optimal value / Q function: $V^\star := V^{\pi^\star}$, $Q^\star := Q^{\pi^\star}$
- optimal policy $\pi^\star(s) = \text{argmax}_{a \in \mathcal{A}} Q^\star(s, a)$

Bellman's optimality principle

Bellman operator:

$$\mathcal{T}(Q)(s,a) := \underbrace{r(s,a)}_{\text{immediate reward}} + \gamma \mathop{\mathbb{E}}_{s' \sim P(\cdot|s,a)} \Big[\underbrace{\max_{a' \in \mathcal{A}} Q(s',a')}_{\text{next state's value}} \Big]$$

- one-step look-ahead

Bellman's optimality principle

Bellman operator:

$$\mathcal{T}(Q)(s,a) := \underbrace{r(s,a)}_{\text{immediate reward}} + \gamma \mathop{\mathbb{E}}_{s' \sim P(\cdot|s,a)} \Big[\underbrace{\max_{a' \in \mathcal{A}} Q(s',a')}_{\text{next state's value}} \Big]$$

- one-step look-ahead

Bellman equation: $Q^\star$ is *unique* solution to

$$\mathcal{T}(Q^\star) = Q^\star$$

γ-contraction of Bellman operator:

$$\|\mathcal{T}(Q_1) - \mathcal{T}(Q_2)\|_\infty \leq \gamma \|Q_1 - Q_2\|_\infty$$

Is Q-learning sub-optimal, or is it an analysis artifact?

A sharpened sample complexity of Q-learning

Theorem (Li, Cai, Chen, Wei, Chi, OR 2024)

For any $0 < \varepsilon \leq 1$, *Q-learning yields* $\|\widehat{Q} - Q^\star\|_\infty \leq \varepsilon$ *with sample complexity at most*

$$\widetilde{O}\left(\frac{|\mathcal{S}||\mathcal{A}|}{(1-\gamma)^4\varepsilon^2}\right).$$

- Improves dependency on the effective horizon $\frac{1}{1-\gamma}$.

A sharpened sample complexity of Q-learning

Theorem (Li, Cai, Chen, Wei, Chi, OR 2024)

For any $0 < \varepsilon \leq 1$, *Q-learning yields* $\|\widehat{Q} - Q^\star\|_\infty \leq \varepsilon$ *with sample complexity at most*

$$\widetilde{O}\left(\frac{|\mathcal{S}||\mathcal{A}|}{(1-\gamma)^4\varepsilon^2}\right).$$

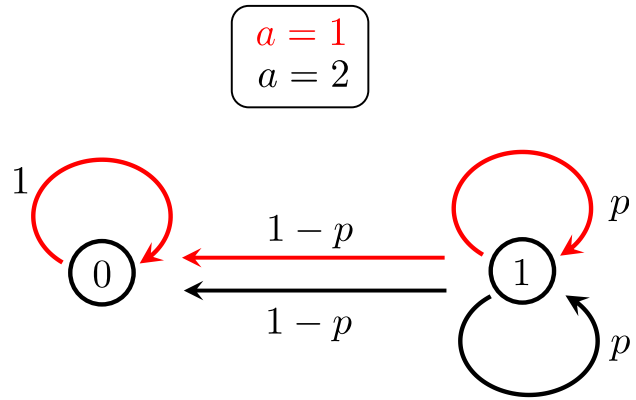
- Improves dependency on the effective horizon $\frac{1}{1-\gamma}$.
- Allows both constant and rescaled linear learning rate:

$$\frac{1}{1+\frac{c_1(1-\gamma)T}{\log^2 T}} \leq \eta_t \leq \frac{1}{1+\frac{c_2(1-\gamma)t}{\log^2 T}}$$

A curious numerical example

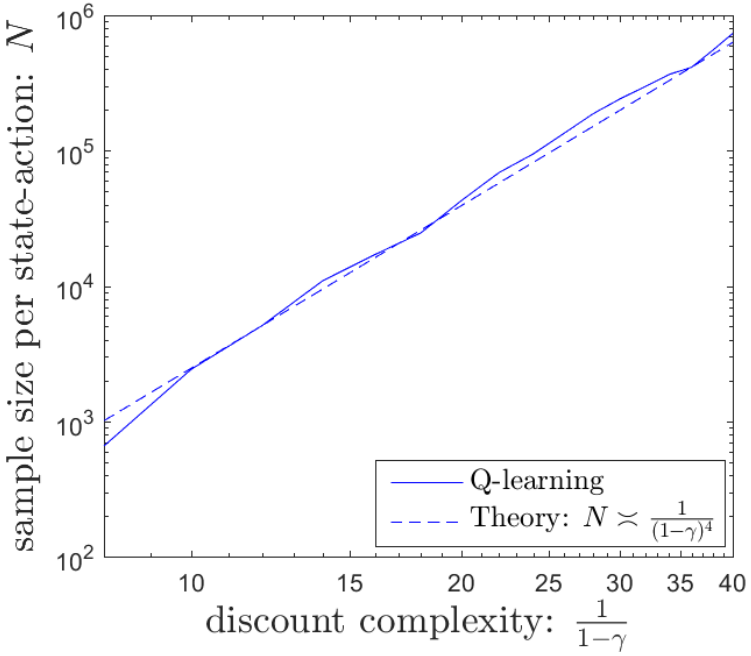
Numerical evidence: $\frac{|\mathcal{S}||\mathcal{A}|}{(1-\gamma)^4\varepsilon^2}$ samples seem necessary ...

— observed in Wainwright '19



$$p = \frac{4\gamma - 1}{3\gamma}$$

$$r(0,1) = 0, \quad r(1,1) = r(1,2) = 1$$



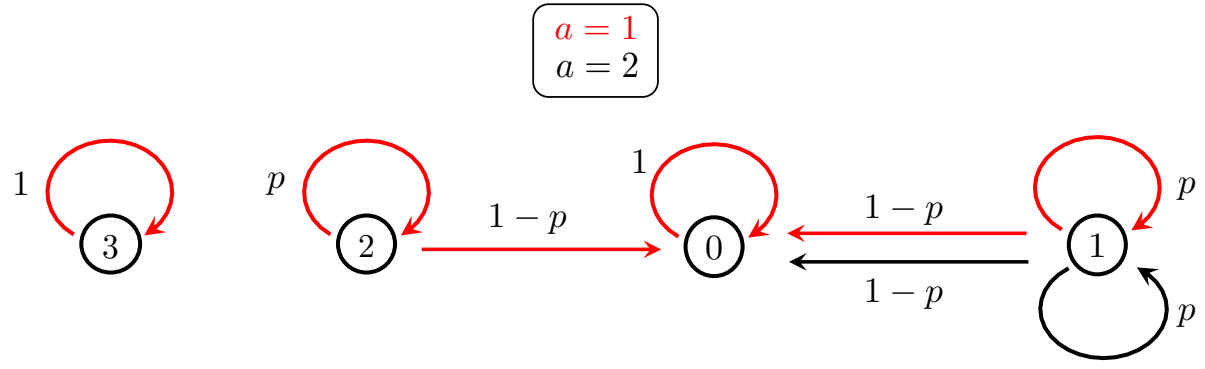
Q-learning is not minimax optimal

Theorem (Li, Cai, Chen, Wei, Chi, OR 2024)

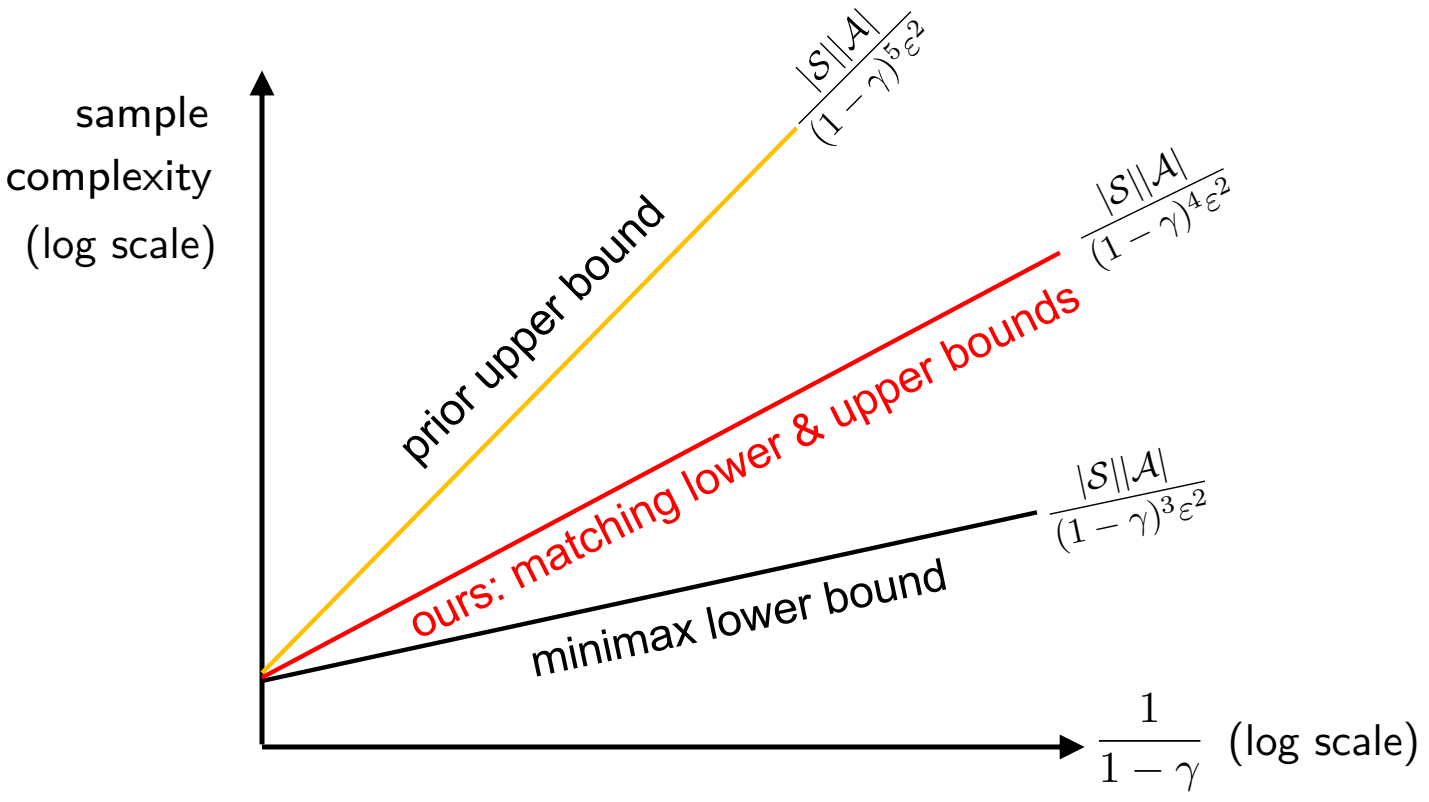
Assume $3/4 < \gamma \leq 1$. For any $0 < \varepsilon \leq 1$, there exists some MDP such that to achieve $\|\widehat{Q} - Q^\star\|_\infty \leq \varepsilon$, Q-learning needs at least a sample complexity of

$$\widetilde{\Omega}\left(\frac{|\mathcal{S}||\mathcal{A}|}{(1-\gamma)^4\varepsilon^2}\right).$$

- Tight **algorithm-dependent** lower bound
- Holds for both constant and rescaled linear learning rates

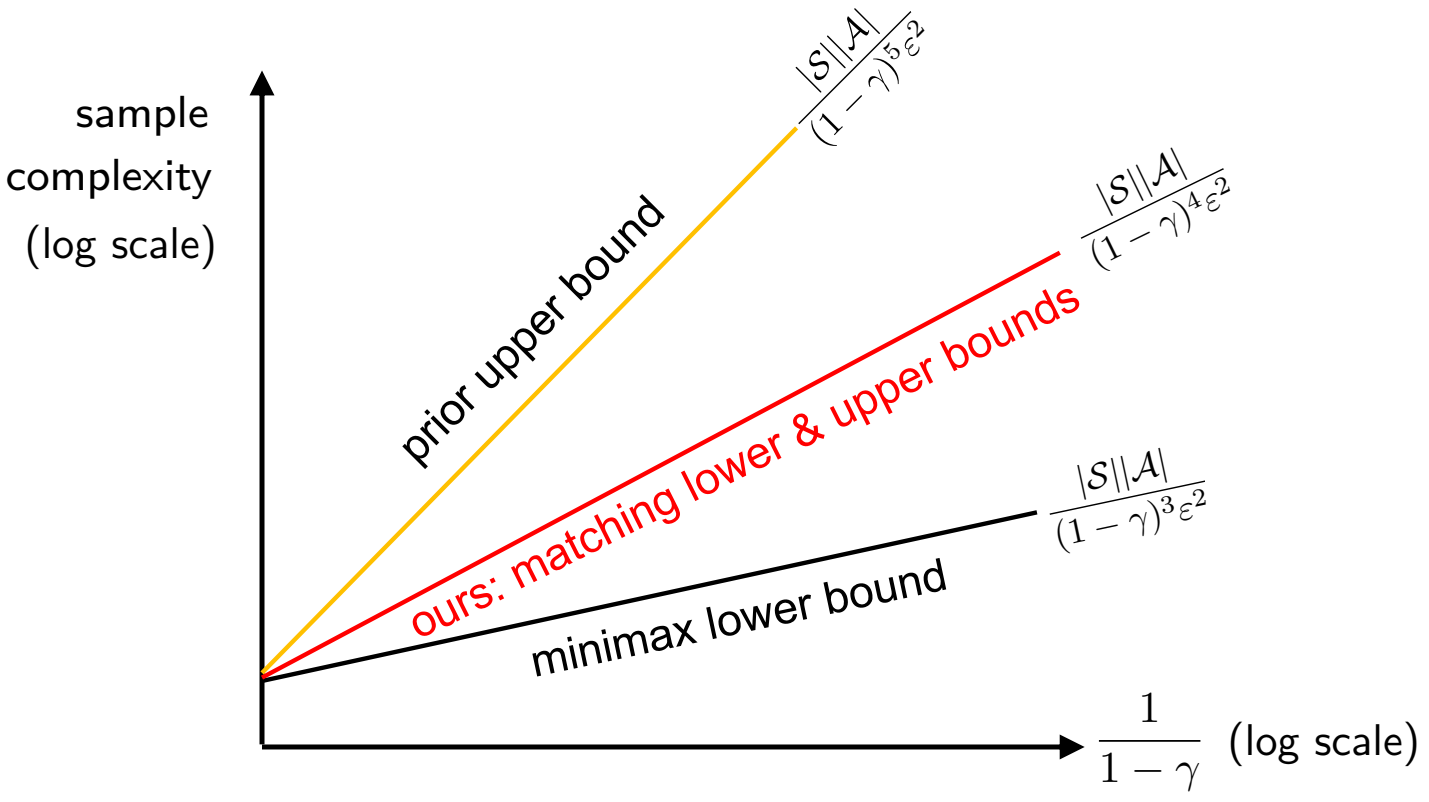


Where we stand now



Q-learning requires a sample size of $\frac{|\mathcal{S}||\mathcal{A}|}{(1-\gamma)^4\varepsilon^2}$.

Where we stand now



Q-learning is not minimax optimal!

Why is Q-learning sub-optimal?

Over-estimation of Q-functions (Thrun and Schwartz, 1993; Hasselt, 2010):

- $\max_{a \in \mathcal{A}} \mathbb{E}X(a)$ tends to be over-estimated (high positive bias) when $\mathbb{E}X(a)$ is replaced by its empirical estimates using a small sample size;
- often gets worse with a large number of actions (Hasselt, Guez, Silver, 2015).
- Motivated the design of double Q-learning (Hasselt, 2010).

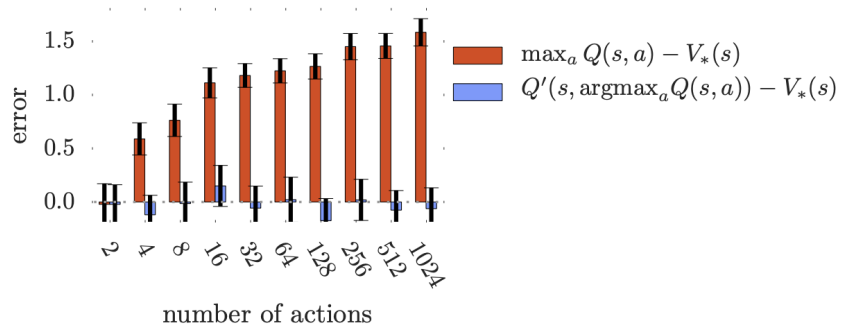


Figure 1: The orange bars show the bias in a single Q-learning update when the action values are $Q(s,a) = V_*(s) + \epsilon_a$ and the errors $\{\epsilon_a\}_{a=1}^m$ are independent standard normal random variables. The second set of action values Q', used for the blue bars, was generated identically and independently. All bars are the average of 100 repetitions.

Why is Q-learning sub-optimal?

Over-estimation of Q-functions (Thrun and Schwartz, 1993; Hasselt, 2010):

- Motivated the design of double Q-learning (Hasselt, 2010).

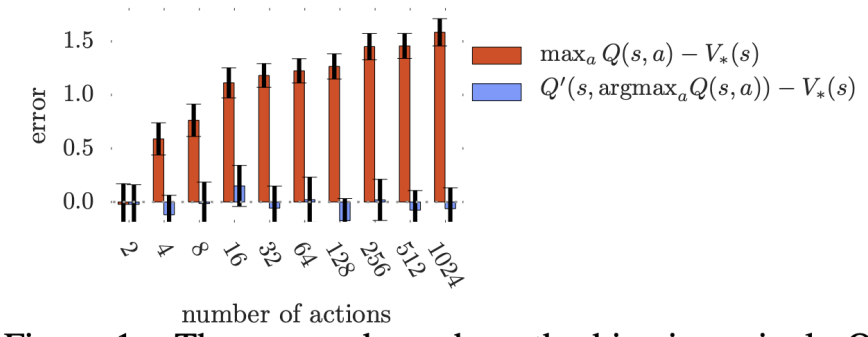

Figure 1: The orange bars show the bias in a single Q-learning update when the action values are $Q(s,a) = V_*(s) + \epsilon_a$ and the errors $\{\epsilon_a\}_{a=1}^m$ are independent standard normal random variables. The second set of action values Q', used for the blue bars, was generated identically and independently. All bars are the average of 100 repetitions.

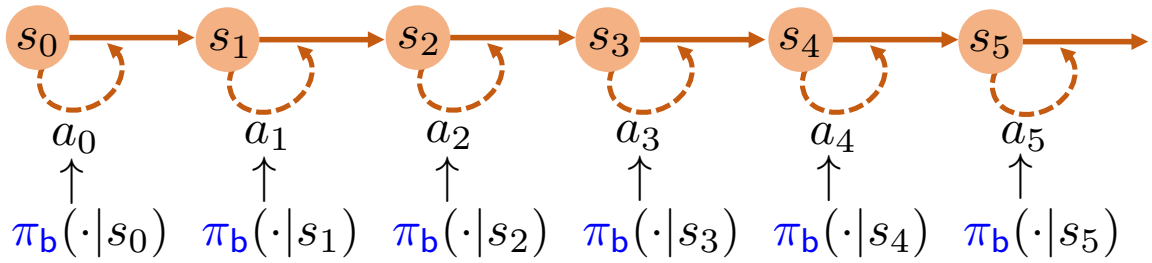
Our work provides theoretical footings regarding the over-estimation issue of vanilla Q-learning.

Asynchronous Q-learning



Stochastic approximation for solving Bellman equation $Q^\star = \mathcal{T}(Q^\star)$ using samples collected from a behavior policy π_b:

$$\underbrace{Q_{t+1}(s_t,a_t) = (1-\eta)Q_t(s_t,a_t) + \eta\mathcal{T}_t(Q_t)(s_t,a_t)}, \quad t \geq 0$$

only update (s_t,a_t)-th entry

How Apple personalizes Siri without hoovering up your data

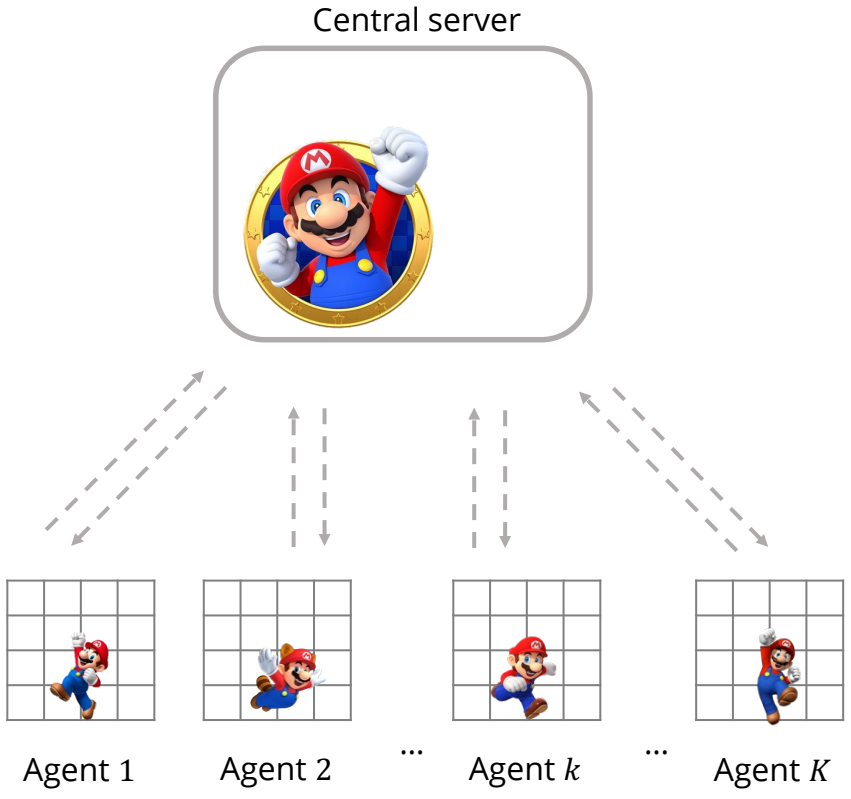
The tech giant is using privacy-preserving machine learning to improve its voice assistant while keeping your data on your phone.

By Karen Hao

December 11, 2019

Federated supervised learning is deployed nowadays by companies in many areas, e.g., on-device inference.

RL meets federated learning



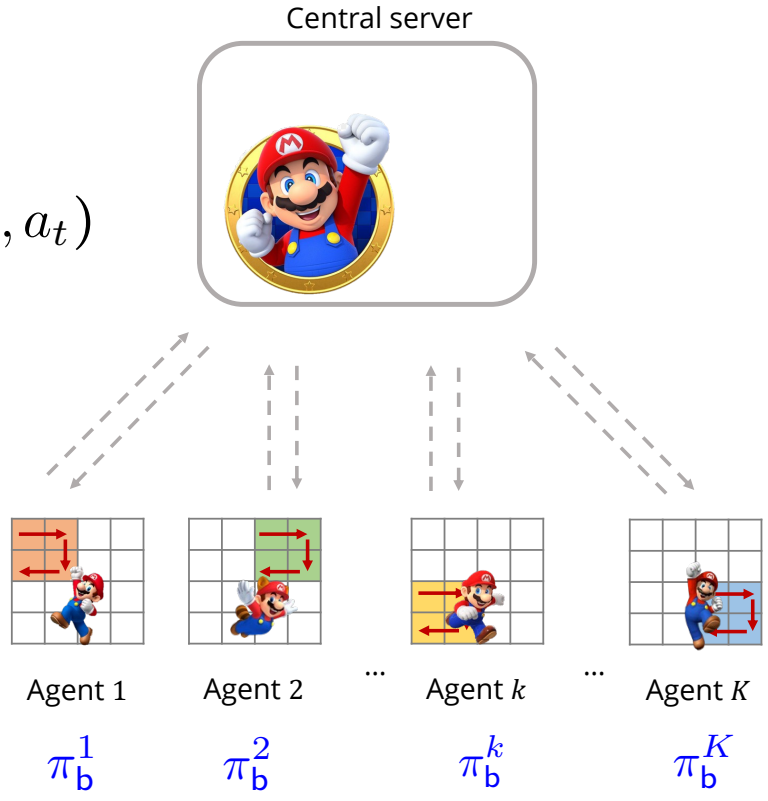
Federated reinforcement learning: enables multiple agents to collaboratively learn a global policy without sharing datasets.

Federated asynchronous Q-learning with local updates

- **Local Q-update:** agent k performs τ rounds of local Q-learning updates:

$$Q_{t+1}^k(s_t, a_t) \leftarrow (1-\eta) Q_t^k(s_t, a_t) + \eta \mathcal{T}_t(Q_t^k)(s_t, a_t)$$

and sends it to the server.



Federated asynchronous Q-learning with local updates

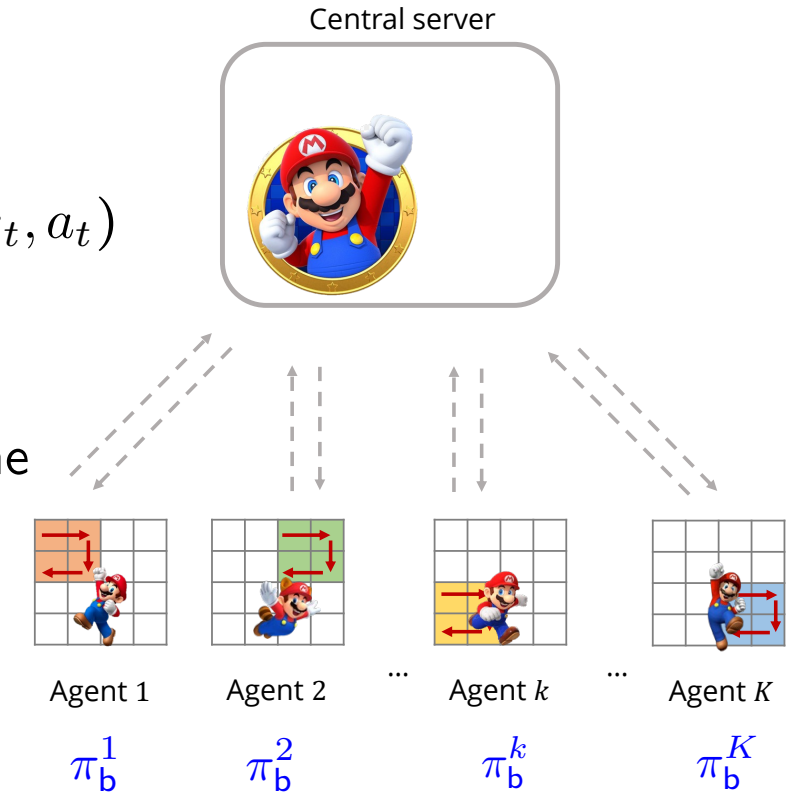
- **Local Q-update:** agent k performs τ rounds of local Q-learning updates:

$$Q_{t+1}^k(s_t,a_t) \leftarrow (1-\eta)Q_t^k(s_t,a_t)+\eta\mathcal{T}_t(Q_t^k)(s_t,a_t)$$

  and sends it to the server.

- **Periodic averaging:** the server averages the local updates and communicates it back to agents:

$$Q_t = \frac{1}{K}\sum_{k=1}^{K} Q_t^k$$



Federated asynchronous Q-learning with local updates

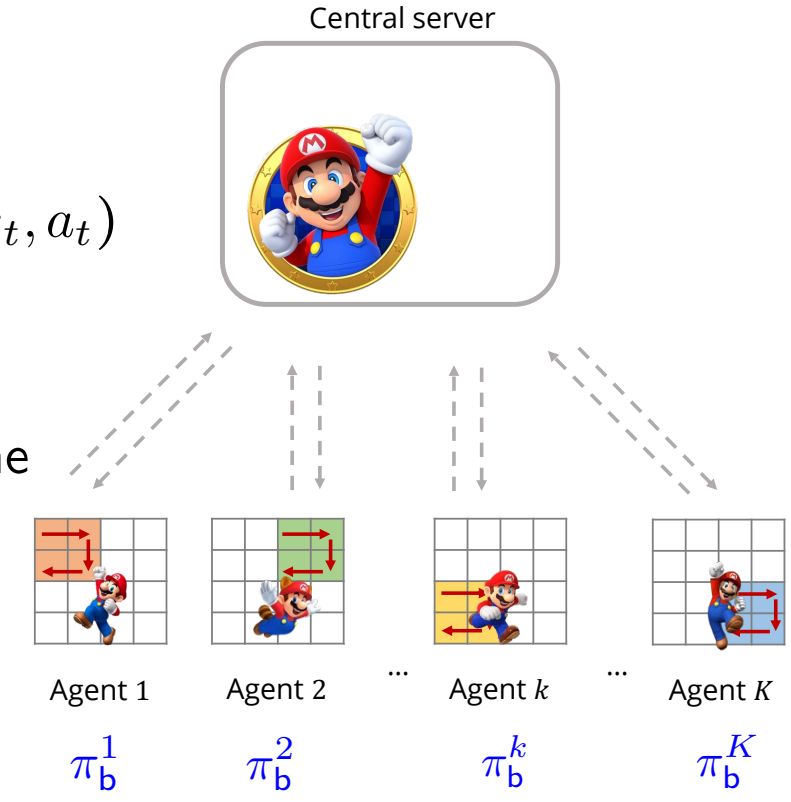
- **Local Q-update:** agent k performs τ rounds of local Q-learning updates:

$$Q_{t+1}^k(s_t,a_t) \leftarrow (1-\eta)Q_t^k(s_t,a_t)+\eta\mathcal{T}_t(Q_t^k)(s_t,a_t)$$

  and sends it to the server.

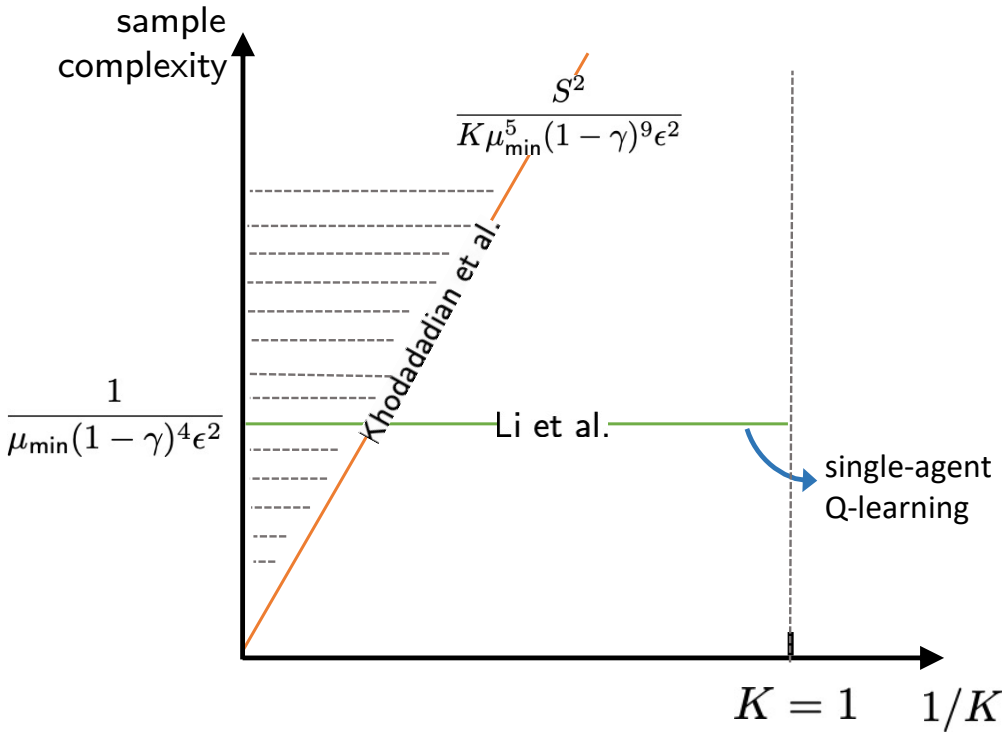
- **Periodic averaging:** the server averages the local updates and communicates it back to agents:

$$Q_t = \frac{1}{K}\sum_{k=1}^{K} Q_t^k$$



Can we achieve faster convergence with heterogeneous local behavior policies with low communication complexity?

Prior art

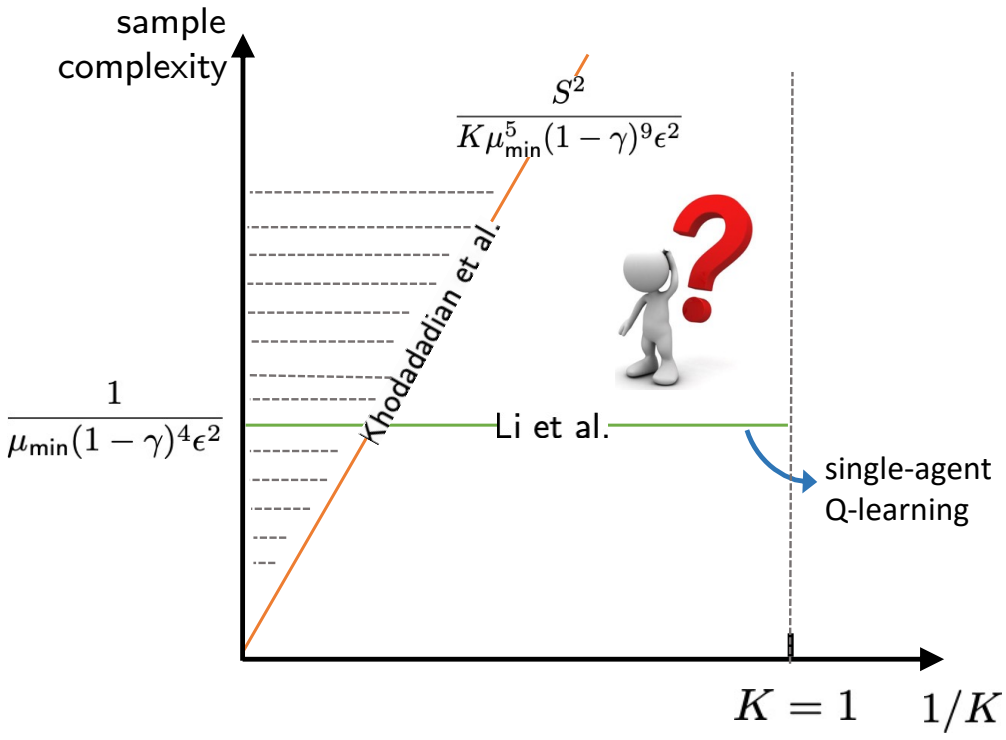


Key quantity: minimum state-action occupancy probability

$$\mu_{\min} := \min_{i,s,a} \underbrace{\mu_{\pi_b^i}(s,a)}_{\text{stationary distribution}}$$

Linear speedup only when $K \gg \frac{S^2}{\mu_{\min}^4(1-\gamma)^5}$

Prior art



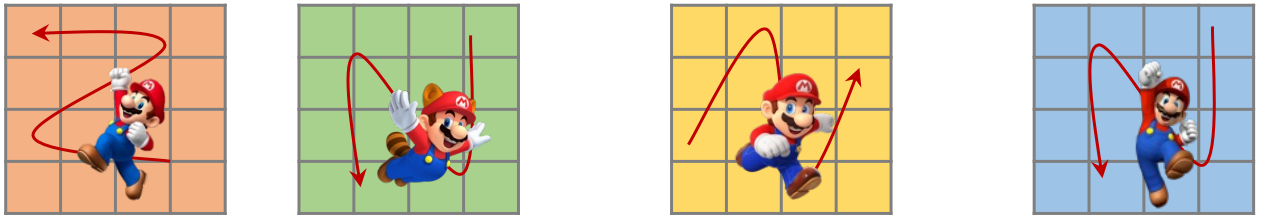
Key quantity: minimum state-action occupancy probability

$$\mu_{\min} := \min_{i,s,a} \underbrace{\mu_{\pi_b^i}(s,a)}_{\text{stationary distribution}}$$

But more curiously...

The benefit of collaboration?

Prior art requires **full coverage** of every agent over the entire state-action space (i.e., $\mu_{\min} > 0$)...



Agent 1 Agent 2 ... Agent k ... Agent K

The benefit of collaboration?

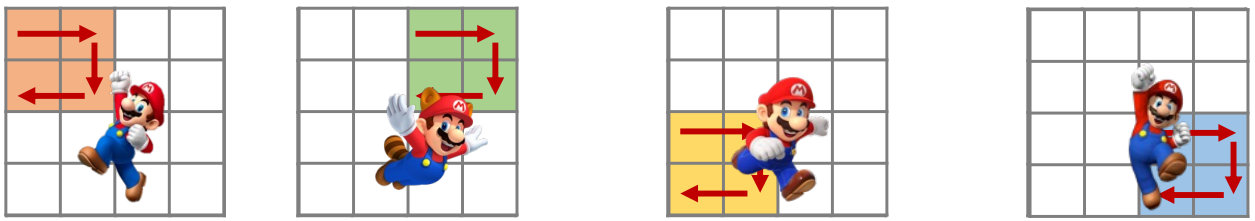
Agent 1 Agent 2 ... Agent k ... Agent K

However, the power of collaboration really shines if we only need...



Agent 1 Agent 2 ... Agent k ... Agent K

Can we enable collaborative coverage while improve the dependency on salient parameters?

Key metrics

Collaborative coverage: minimum entry of the average stationary distribution

$$\mu_{\mathsf{avg}} = \min_{s,a} \frac{1}{K} \sum_{k=1}^{K} \mu_{\mathsf{b}}^{k}(s,a) \geq \mu_{\mathsf{min}}.$$

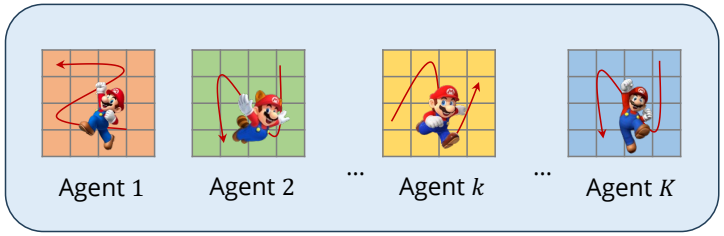
Key metrics

Collaborative coverage: minimum entry of the average stationary distribution

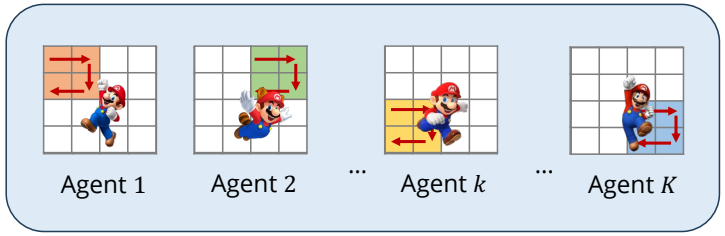
$$\mu_{\mathsf{avg}} = \min_{s,a} \frac{1}{K} \sum_{k=1}^{K} \mu_{\mathsf{b}}^{k}(s,a) \geq \mu_{\mathsf{min}}.$$

Heterogeneity of local behavior policies: density ratio of individual / average behavior policies

$$C_{\mathsf{het}} = K \max_{k,s,a} \frac{\mu_{\mathsf{b}}^{k}(s,a)}{\sum_{k=1}^{K} \mu_{\mathsf{b}}^{k}(s,a)} = \max_{k,s,a} \frac{\mu_{\mathsf{b}}^{k}(s,a)}{\mu_{\mathsf{avg}}(s,a)}.$$



$C_{\mathsf{het}} = 1$



$C_{\mathsf{het}} = K$

Our theorem

Theorem (Woo, Joshi, Chi, 2023+)

For sufficiently small $\varepsilon > 0$, federated asynchronous Q-learning yields $\|\widehat{Q} - Q^\star\|_\infty \le \varepsilon$ with sample complexity at most

$$\widetilde{O}\left(\frac{C_{\mathsf{het}}}{K\mu_{\mathsf{avg}}(1-\gamma)^5\varepsilon^2}\right)$$

ignoring the burn-in cost that depends on the mixing times.

Our theorem

Theorem (Woo, Joshi, Chi, 2023+)

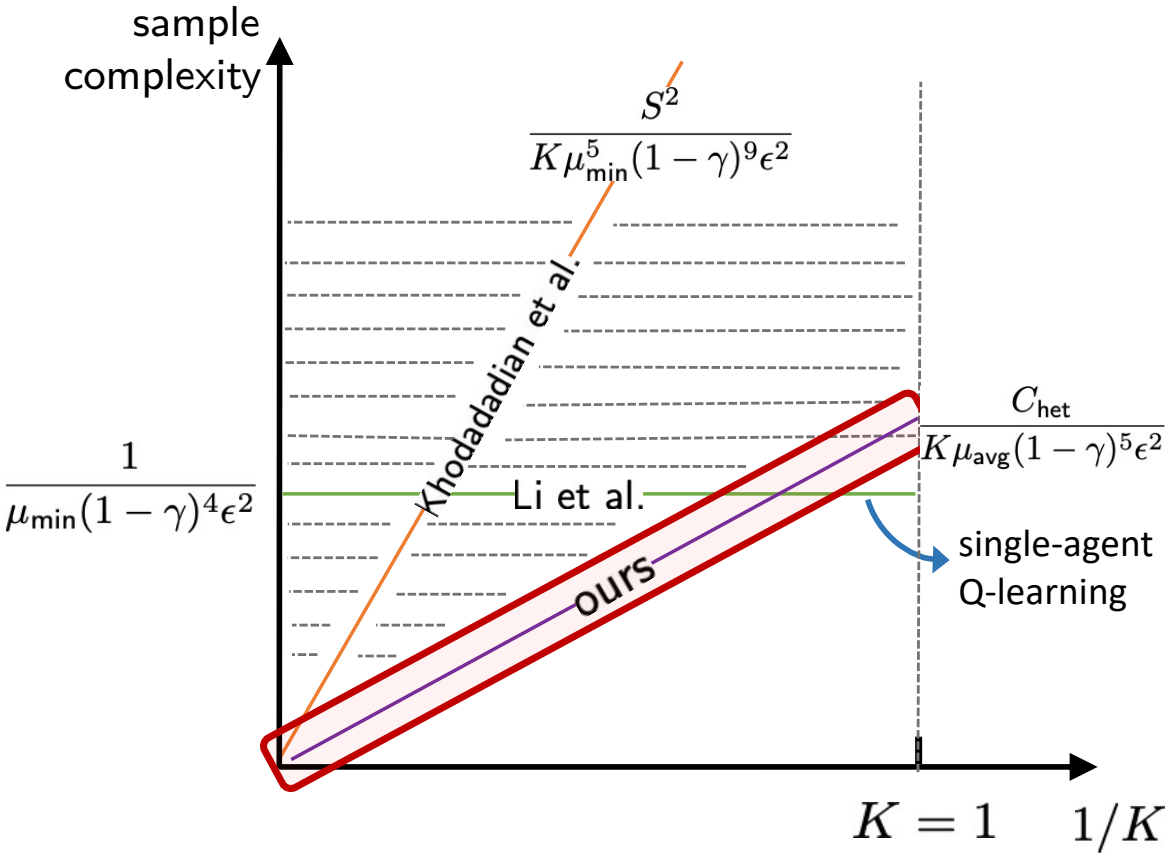
For sufficiently small $\varepsilon > 0$, federated asynchronous Q-learning yields $\|\widehat{Q} - Q^\star\|_\infty \le \varepsilon$ with sample complexity at most

$$\widetilde{O}\left(\frac{C_{\mathsf{het}}}{K\mu_{\mathsf{avg}}(1-\gamma)^5\varepsilon^2}\right)$$

ignoring the burn-in cost that depends on the mixing times.

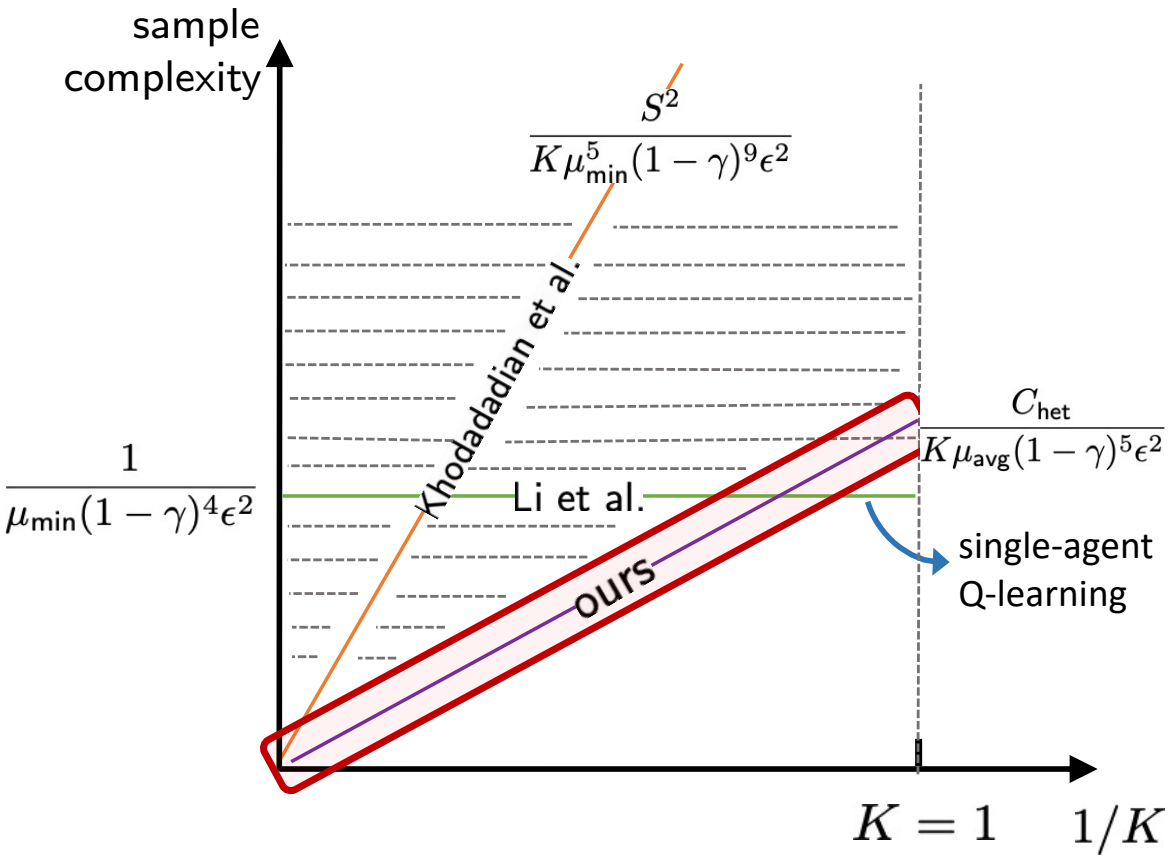
- Near-optimal linear speedup when the local behavior policies are similar, $C_{\mathsf{het}} \approx 1$.
- Key idea: leave-one-out type arguments to decouple complicated statistical dependencies due to Markovian sampling and local updates.

Comparison with prior art



Linear speedup with near-optimal parameter dependencies!

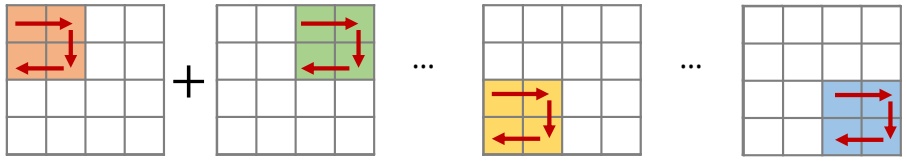
Curse of heterogeneity?



Still not good enough! Performance degenerates when local behavior policies are heterogeneous (i.e. $1 \ll C_{\text{het}}$). ☹

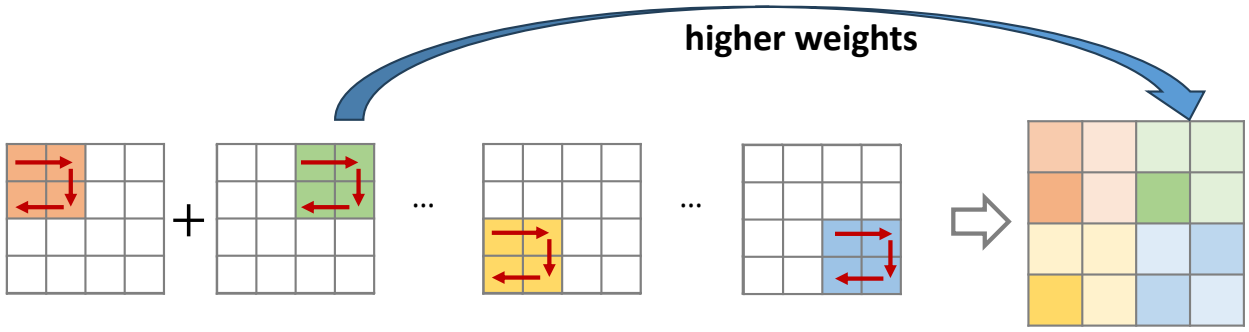
Importance averaging

Key observation: not all updates are of same quality due to limited visits induced by the behavior policy.



Importance averaging

Key observation: not all updates are of same quality due to limited visits induced by the behavior policy.



Importance averaging: the server averages the local updates based on importance via

$$Q_t(s,a) = \frac{1}{K}\sum_{k=1}^{K} \alpha_t^k(s,a) Q_t^k(s,a),$$

where

$$\alpha_t^k = \frac{(1-\eta)^{-N_{t-\tau,t}^k(s,a)}}{\sum_{k=1}^{K}(1-\eta)^{-N_{t-\tau,t}^k(s,a)}}, \qquad N_{t-\tau,t}^k(s,a) = \text{number of visits in the sync period}.$$

Our theorem

Theorem (Woo, Joshi, Chi, 2023+)

For sufficiently small $\varepsilon > 0$, federated asynchronous Q-learning with importance averaging yields $\|\widehat{Q} - Q^\star\|_\infty \leq \varepsilon$ with sample complexity at most

$$\widetilde{O}\left(\frac{1}{K\mu_{\mathsf{avg}}(1-\gamma)^5\varepsilon^2}\right)$$

ignoring the burn-in cost that depends on the mixing times.

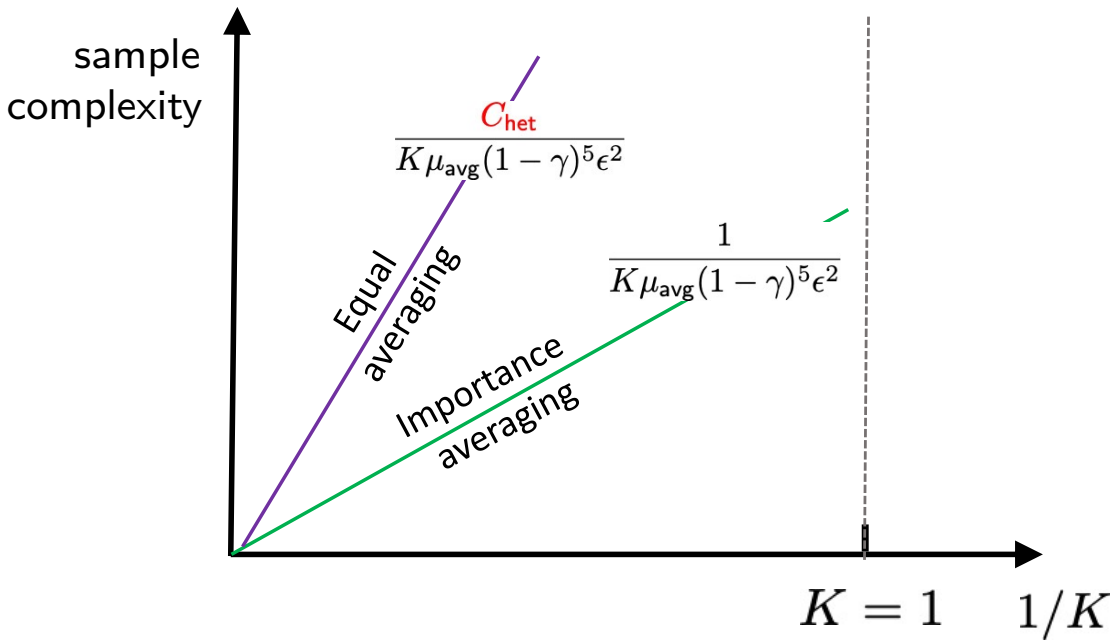
Our theorem

Theorem (Woo, Joshi, Chi, 2023+)

For sufficiently small $\varepsilon > 0$, federated asynchronous Q-learning with importance averaging yields $\|\widehat{Q} - Q^\star\|_\infty \le \varepsilon$ with sample complexity at most

$$\widetilde{O}\left(\frac{1}{K\mu_{\mathsf{avg}}(1-\gamma)^5\varepsilon^2}\right)$$

ignoring the burn-in cost that depends on the mixing times.

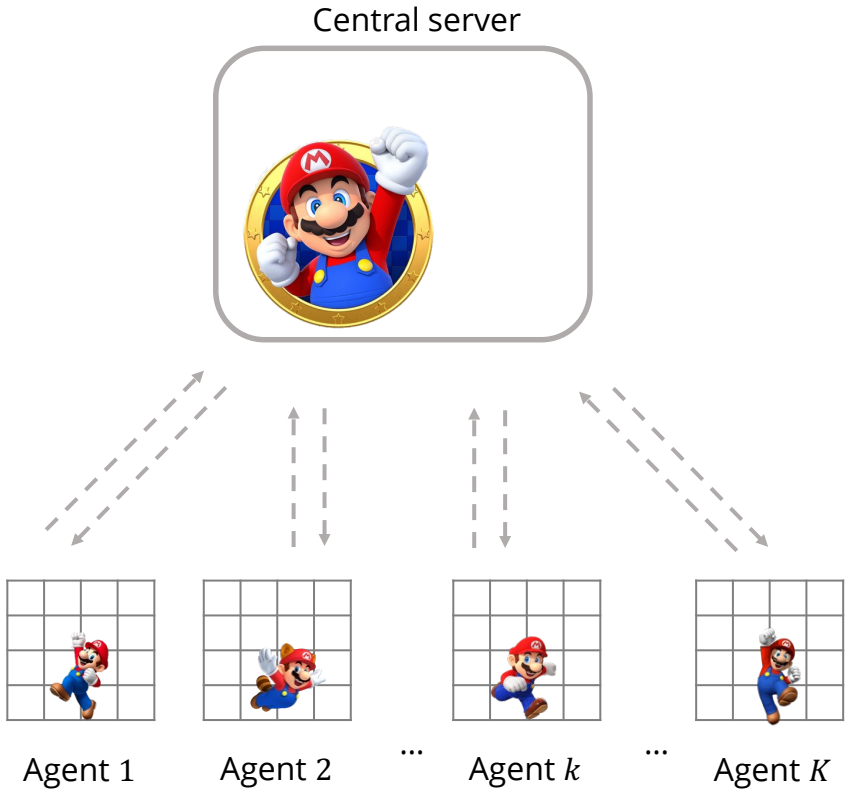


The statistical-communication complexity trade-off in federated Q-Learning

Sudeep Salgia

CMU

Communication bottleneck



The price of communication: how much communication do we need to pay to achieve the linear speedup?

A communication lower bound

Theorem (Salgia and Chi, 2024; informal)

For a wide family of federated Q-learning algorithm with intermittent communication, *regardless of the choice of synchronization schedules, the number of communication rounds needs to be at least*

$$\widetilde{\Omega}\left(\frac{1}{1-\gamma}\right)$$

in order to achieve any speedup *with respect to the number of agents.*

A communication lower bound

Theorem (Salgia and Chi, 2024; informal)

For a wide family of federated Q-learning algorithm with intermittent communication, *regardless of the choice of synchronization schedules, the number of communication rounds needs to be at least*

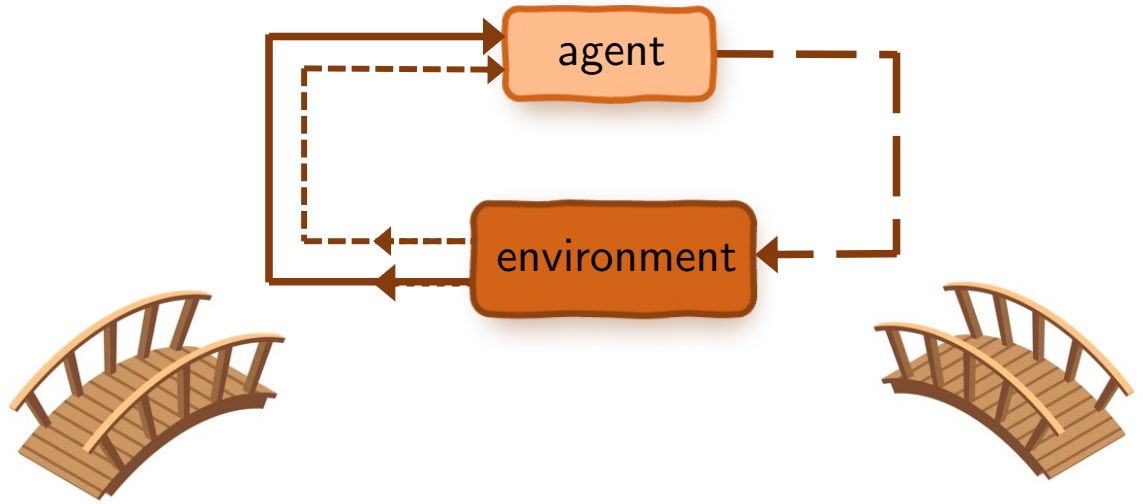
$$\widetilde{\Omega}\left(\frac{1}{1-\gamma}\right)$$

in order to achieve any speedup *with respect to the number of agents.*

- The lower bound is established for the same hard instance earlier.
- **Fed-DVR-Q:** it is possible to design algorithms with near-optimal statistical and communication complexities in the synchronous setting:

$$\widetilde{O}\left(\frac{|\mathcal{S}||\mathcal{A}|}{K(1-\gamma)^3\varepsilon^2}\right) \text{ samples,} \qquad \widetilde{O}\left(\frac{1}{1-\gamma}\right) \text{ rounds.}$$

Summary



Single-agent Q-learning

Vanilla Q-learning is not minimax-optimal!

Federated Q-learning

Linear speedup even with heterogenous behavior policies!

Summary
